

# Renaming Trick

```
In [2]: %matplotlib inline
import pandas as pd
import numpy as np
import matplotlib.pyplot as plt
from scipy import stats
from matplotlib.backends.backend_pdf import PdfPages
```

In [ ]:

This reads in our well data like normal

```
In [4]: df=pd.read_csv('well_data.csv')
```

## To do list

- Open the r2 excel file you made in class. I called it r2\_class\_example.xlsx
- add a new column. Call it something like new\_name. Give it new names.
- Save the file to a new name so it can't get over written. I called it r2\_class\_example\_new\_names.xlsx
- read it in and call it something useful
- set the index column to name.

```
In [7]: df_name=pd.read_excel('r2_class_example_new_names.xlsx',index_col='name')
```

In [18]: df\_name

	Unnamed: 0	r2	new_name
name			
<b>Sr</b>	11	0.155595	Stronitium (pp=b)
<b>Ca</b>	3	0.154148	Calcium (ppb)
<b>P</b>	1	0.069488	Phosphourous (ppm)
<b>Fe</b>	4	0.065557	Fe (mgL <sup>-1</sup> )
<b>Ba</b>	5	0.059968	ppm
<b>Na</b>	6	0.053342	Sodium is boring
<b>Si</b>	0	0.037977	Si (ppb)
<b>Mn</b>	9	0.032770	I hate units!
<b>SO4</b>	14	0.021915	ppm
<b>Br</b>	15	0.018130	ppm
<b>S</b>	2	0.014789	Sulfur $\left(\frac{\mu g}{L}\right)$
<b>Cl</b>	13	0.009093	ppb
<b>Mg</b>	7	0.000824	ppm
<b>K</b>	8	0.000090	something else?
<b>F</b>	12	0.000030	ppm

Here is what we can do.

- We can pass the element name into df\_name and try to get out the new name.
- below is my bad schematic of using a dataframe as a converter.
- We do this by asking for the new\_name column and passing in the index.

- There are a couple ways to do this.

```
In [26]: from IPython.display import Image
Image(filename='converter.jpg', width=300)
```

```
In [14]: el='Fe'
df_name['new_name'][el]
```

```
Out[14]: 'Fe (mgL^{-1})'
```

```
In [16]: el='Fe'
df_name.loc[el]['new_name']
```

```
Out[16]: 'Fe (mgL^{-1})'
```

Now change el to a different element.

```
In [19]: el='Ca'
df_name.loc[el]['new_name']
```

```
Out[19]: 'Calcium (ppb)'
```

Now this is confusing.

- loop over the columns in df
- check if the column name is in the index of df\_name
- if yes print the old and new name

```
In [23]: for col in df:
    if col in df_name.index:
        print('The original column name is {} and now I can convert it to {}'.format(col, df_name.loc[col]['new_name']))
    else:
        print('not in index')
```

```
not in index
The original column name is Si and now I can convert it to Si (ppb)
The original column name is P and now I can convert it to Phosphourous (ppm)
The original column name is S and now I can convert it to Sulfur $\left(\frac{\mu g}{L}\right)$
The original column name is Ca and now I can convert it to Calcium (ppb)
The original column name is Fe and now I can convert it to Fe (mgL^{-1})
The original column name is Ba and now I can convert it to ppm
The original column name is Na and now I can convert it to Sodium is boring
The original column name is Mg and now I can convert it to ppm
The original column name is K and now I can convert it to something else?
The original column name is Mn and now I can convert it to I hate units!
not in index
The original column name is Sr and now I can convert it to Stronitum (pp=b)
The original column name is F and now I can convert it to ppm
The original column name is Cl and now I can convert it to ppb
```

The original column name is S04 and now I can convert it to ppm

The original column name is Br and now I can convert it to ppm

Now here I am going to use the trick to change an axis name

```
In [25]: fig,ax=plt.subplots()

x='As'
y='Fe'

props=dict(boxstyle='round', facecolor='coral', alpha=0.5)
print (y)

if df[y].dtype==float:
    ax.scatter(df[x],df[y])
    ax.set_xlabel(x, fontsize=14)
    ax.set_ylabel(df_name.loc[y]['new_name'], fontsize=14)

    results=stats.linregress(df[[x,y]].dropna())

    textstr='m={:.3f}\nb={:.3f}\nr^2={:.3f}\np={:.3f}'.\
        format(results.slope,results.intercept\
               ,results.rvalue**2,results.pvalue)

    x_fit=np.array([df[x].min(),df[x].max()])
    ax.plot(x_fit,results.slope*x_fit+results.intercept,color='gray',linestyle='dotted')

    ax.text(0.75,0.95,textstr,transform=ax.transAxes, fontsize=14\
            ,verticalalignment='top',bbox=props)
```

Fe
